# Lab 2--Python Cloud Project (Lambda)

## Data Engineering Diploma

Content developed by: WeCloudData Academy

## 1. Project Description

In this project, you need to read data from a relational database (MySQL), save the result to S3, and finally post your result to an API endpoint. Here is the general architecture:

## 2. Detail Steps

1. Start a MySQL database on AWS RDS and connect RDS with MySQL Workbench. If you don't know how to set this, please watch the (video.)
2. Download the sql script from the **DOWNLOADS**. And run the script on MySQL to load data. You will have a database called **superstore**.

3. Query the database, to get the top 10 customer ids who have the most purchase. Get their **customer id** and **sum of the customer sales** (you can use different column name) from the database.

4. After getting the result, save the result to S3. In order to do so:

   - 1) You need to create an EC2 instance and build a python project.
   - 2) Use the python script to bring the result from MySQL to EC2. The result includes the **customer id** and the **sum of the customer sales** of the top 10 customers.
   - 3) Save the result as a **.json** file locally in EC2.
   - 4) Upload the file from EC2 to S3. The file should be in an 'input' folder in the S3 bucket.

5. When the file lands on the S3 bucket, a lambda is triggered. The lambda function will:

   - 1) get the **customer id** list from the S3 **..json** file;
   - 2) query the customer names from the database based on the **customer id** list.
   - 3) send a JSON data, including **customer id** , **customer name** and **today's date** to an API endpoint. The API endpoint is: https://virtserver.swaggerhub.com/wcd_de_lab/top10/1.0.0/add
   - 4) Here are some tips for the lambda function:
     - When you create a lambda function, you may need a lambda layer to install 3rd party libraries. This is an article about how to add a layer.(article)
     - Put the **customer id**, **customer name** and **today's date** (format: '1990-01-01') in a JSON structure variable, such as data. (But the variable is a string).

```json
[
    {
        "id":91811409,
        "name":"Ritsa Hightower",
        "date":"2022-06-28"
    },
    {
        "id":64444841,
        "name":"Becky Pak",
        "date":"2022-06-28"
    },
    {
        "id":38079848,
        "name":"Raymond Book",
        "date":"2022-06-28"
    },
    {
        "id":104752832,
        "name":"Jasper Cacioppo",
        "date":"2022-06-28"
    },
    {
        "id":23905406,
        "name":"Dennis Kane",
        "date":"2022-06-28"
    },
```

     - Use POST to send data. Here is what the final API data looks like:
     - When the **POST** Succeed, the return code should be **201**. Use the **status_code** method in requests to get the returned code.
   - 5) Use python project structure.
   - 6) Use git repository to save your code.
